Enhanced External Counterpulsation (EECP)

Policy Number:  2.02.06  
Origination:  10/2003  
Last Review:  10/2017  
Next Review:  10/2018

**Policy**

Blue Cross and Blue Shield of Kansas City (Blue KC) will provide coverage for enhanced external counterpulsation when the criteria shown below are met.

---

**When Policy Topic is covered**

External Counterpulsation may be considered **medically necessary** for patients with severe chronic stable angina who are not considered suitable candidates for angioplasty or revascularization or who have continuing angina despite surgical intervention.

---

**When Policy Topic is not covered**

External Counterpulsation is considered **investigational** for the following patients:

- Patients with severe chronic stable angina who are considered suitable candidates for angioplasty or revascularization. This is based on evidence that ECP therapy may provide similar outcomes in these patients as well as those who are not candidates for angioplasty or revascularization, but that relief of angina may be superior following coronary intervention.

- Patients with other cardiac conditions, such as congestive heart failure, acute MI, unstable angina, or cardiogenic shock. This is based on the lack of evidence regarding the safety and efficacy of ECP in these patient populations.

- Patients with specific contraindications for this therapy, including cardiac catheterization within 2 weeks; arrhythmia; severe congestive heart failure with ejection fraction <30%; aortic insufficiency; peripheral vascular disease or phlebitis; severe hypertension (> 180/110 mm Hg); bleeding diathesis; pregnancy. This reflects concerns regarding the safety of ECP when used in the presence of these conditions

- Patients with erectile dysfunction.

- Patients with ischemic stroke.

Enhanced external counterpulsation (EECP) is a noninvasive treatment used to augment diastolic pressure, decrease left ventricular afterload, and increase venous return. It has been studied primarily as a treatment for patients with refractory angina and heart failure.

For individuals who have chronic stable angina who receive enhanced external counterpulsation (EECP), the evidence includes randomized controlled trials (RCTs), observational studies, and systematic reviews. Relevant outcomes are overall survival, symptoms, morbid events, and functional outcomes. There is only 1 blinded randomized controlled trial (RCT) that includes clinical outcomes, and this trial reported benefit on only 1 of 4 main angina outcomes. Additional small RCTs report changes in physiologic measures associated with EECP but do not provide relevant evidence on clinical efficacy. Because of the variable natural history of angina, the multiple confounding variables for cardiac outcomes, and the potential for a placebo effect, RCT evidence is needed. Therefore, observational studies, including registry studies with large numbers of patients, add little to determinations of efficacy. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have heart failure who receive EECP, the evidence includes RCTs, observational studies, and systematic reviews. Relevant outcomes are overall survival, symptoms, morbid events, and functional outcomes. One RCT that reported on clinical outcomes reported a modest benefit with EECP on some outcomes and no benefit on others. A second RCT reported improvements on the 6 minute walk test with EECP, but has methodological limitations that limit conclusions that can be drawn. The observational studies on EECP in heart failure have limited ability to inform the evidence on EECP due to the multiple confounding variables for cardiac outcomes and the potential for a placebo effect. The evidence is insufficient to determine the effects of the technology on health outcomes.
Background
Enhanced external counterpulsation (EECP) uses timed, sequential inflation of pressure cuffs on the calves, thighs, and buttocks to augment diastolic pressure, decrease left ventricular afterload, and increase venous return. Augmenting diastolic pressure displaces a volume of blood backward into the coronary arteries during diastole when the heart is in a state of relaxation and the resistance in the coronary arteries is at a minimum. The resulting increase in coronary artery perfusion pressure may enhance coronary collateral development or increase flow through existing collaterals. In addition, when the left ventricle contracts, it faces a reduced aortic pressure to work against, since the counterpulsation has somewhat emptied the aorta. EECP has been primarily investigated as a treatment for chronic stable angina.

Intra-aortic balloon counterpulsation is a more familiar, invasive form of counterpulsation that is used as a method of temporary circulatory assistance for the ischemic heart, often after an acute myocardial infarction (MI). In contrast, EECP is thought to provide a permanent effect on the heart by enhancing the development of coronary collateral development. A full course of therapy usually consists of 35 one-hour treatments, which may be offered once or twice daily, usually 5 days per week. The multiple components of the procedure include the use of the device itself, finger plethysmography to follow the blood flow, continuous electrocardiograms (EKGs) to trigger inflation and deflation, and optional use of pulse oximetry to measure oxygen saturation before and after treatment.

Regulatory Status
A variety of enhanced external counterpulsation (EECP) devices have been cleared for marketing by the Food and Drug Administration (FDA) through the 510(k) process. Examples of EECP devices with FDA clearance are outlined in Table 1.

EECP: enhanced external counterpulsation; FDA: Food and Drug Administration; VO2:oxygen consumption.

**Rationale**

This evidence review was created in January 1998 and has been updated regularly with searches of the MEDLINE database. The most recent literature review was performed for the period through July 1, 2016.

Randomized controlled trials (RCTs) that report on relevant clinical outcomes are required to determine whether enhanced external counterpulsation (EECP) is efficacious and whether it is at least as good as alternative treatments. Observational data are of limited utility given the variable natural history of disorders such as angina and/or heart failure, the presence of many potential confounders of cardiac outcomes, and the potential for a placebo effect.

The literature base consists of a small number of RCTs, some of which report relevant clinical outcomes and others that report intermediate, or physiologic, outcome measures. In addition to the small number of RCTs, there are a large number of observational studies, including publications from EECP registries and case series, which generally report pre- and posttreatment measures of EECP effectiveness.

**Chronic Stable Angina**

**TEC Assessments**

The original literature review for this document was based on a 1999 TEC Assessment on EECP for chronic stable angina and updated with 2002 and 2005 TEC Assessments. These assessments concluded that the evidence was insufficient to determine whether EECP improved the net health outcome or is as beneficial as any established alternatives in patients with chronic stable angina.

Specifically, the 2005 TEC Assessment offered the following observations and conclusions regarding EECP for chronic stable angina:

- There is insufficient evidence to draw conclusions about the benefits of EECP.
- The results of the single RCT, the Multicenter Study of Enhanced External Counterpulsation (MUST-EECP) must be interpreted with caution, in view of the high subject dropout rate and uncertainty regarding the clinical significance of the reported improvement in physiologic measures, especially when intent-to-treat analysis is applied.
Comparative studies of EECP do not address the hard outcomes of cardiac death or recurrent cardiac events such as myocardial infarction and revascularization procedures.\(^{(5,6)}\)

Several case series and registry-based studies have reported the outcomes of large numbers of patients treated in a number of different institutions. There are several problems with this kind of evidence. These studies, while contributing to the body of knowledge of EECP, do little to address the efficacy or durability of EECP treatment. The lack of comparison groups makes it impossible to rule out either placebo effect or spontaneous recovery among patients with milder disease.

**Randomized Controlled Trials**

In 1999, Arora et al presented results of the MUST-EECP trial. MUST-EECP applied a randomized controlled, double-blinded protocol that compared active treatment to placebo (inactive counterpulsation [CP] sham treatment) among 139 patients with Canadian Cardiovascular Society (CCS) Classification Scales (a functional assessment tool based on the level of exertion that elicits symptoms) class I-III chronic, stable angina.\(^{(3)}\) Four outcomes were examined:

- Self-reported frequency of angina, analyzed 2 ways;
- Self-reported use of on-demand nitroglycerin;
- Exercise duration tolerance testing; and
- Time to exercise-induced ischemia (defined as time to depression of ≥1mm in the ST segment on electrocardiogram).

All patients underwent the same 35-hour protocol, followed by an exercise tolerance test within 1 week of completion of therapy. Follow-up beyond the treatment period was not conducted. Intention-to-treat analyses were reported for the angina count and nitroglycerin usage outcomes only. There was a statistically significant difference (p=0.01) between groups in the change in time to 1 mm or greater ST segment depression. Patients in the EECP group had an average difference of 37 seconds longer time to ST segment depression compared with the sham-treated group. There was no significant difference between treatment groups in the change in exercise duration from baseline to the posttreatment period (p<0.31). In addition, there were no statistically significant differences between groups with respect to angina counts (p<0.09) or nitroglycerin use (p>0.1).

In addition to a number of methodologic limitations found in the design, execution, and reporting of this study, the magnitude of the benefit reported is not large. Of the 4 end points of interest, only the time to ST segment depression was statistically different in the EECP group compared with the sham-treated group. The clinical significance of a 37-second improvement in time to ST segment depression is unknown, but given that it occurred while the other 3 end points were statistically unchanged with therapy, does not suggest a marked improvement. That both groups showed increased exercise duration suggests a degree of placebo effect; exercise duration possesses a motivational component that time to ST segment depression does not.
In 2002, Arora et al published a 12-month follow-up study to the MUST-EECP trial.(4) However, only 71 (54%) of the original 139 subjects were included in the study. Subjects treated with EECP reported greater improvement in several quality-of-life scales. However, such findings could not be correlated with treatment response reported in the first study (because of data limitations). The findings are further limited by the small sample size and potentially biased sample of the original subject pool.

A small unblinded RCT published in 2012(7) addressed 1 health outcome, change after 7 weeks in CCS angina class, along with multiple intermediate outcomes. Twenty patients with refractory angina (CCS class III) were randomized to EECP or no EECP. Mean CCS class was significantly improved in the EECP group but not in the no EECP group. At 7-week follow-up, soluble interleukin-2 receptor measurements significantly increased in the EECP group and significantly decreased in the no EECP group. There were no differences between groups at 7 weeks in resting cutaneous microvascular blood flow or response to acetylcholine, sodium nitroprusside or local heating.

Additional RCTs have reported on intermediate, or physiologic, outcomes. One such RCT (N=20) was published in 2010 comparing intracoronary blood flows in patients treated with EECP against those treated with a sham procedure.(8) This trial was designed to detect statistically significant differences in collateral flow rates by angiography, not anginal symptoms. After 7 weeks of treatment, collateral flow index increased significantly in the EECP group compared with sham treatment. Similar findings were noted in a comparative study by Buschmann et al of 23 patients published in 2009.(9)

Two publications from a single study reported on blood flow and other measures of arterial function.(10,11) This study randomized 42 patients with coronary artery disease and chronic angina to EECP or sham EECP. EECP improved flow-mediated dilation in the brachial and femoral arteries and improved numerous serum markers of blood flow and inflammation. The same study also reported that measures of arterial stiffness were improved in the EECP group. Martin et al randomized 18 patients with abnormal glucose tolerance to EECP or standard care and reported that measures of glucose tolerance, as well as measures of arterial function, were improved in the EECP group.(12)

In a randomized pilot study, Shakouri et al (2015) reported on intermediate outcome measures, including plasma nitric oxide (NO), endothelin 1, high sensitivity C reactive protein (HSCRP), and quality of life, in patients with coronary artery disease randomized to 20 sessions of EECP (n=21) or cardiac rehabilitation (n=21).(13) There were no statistically significant improvements in physiologic markers and quality of life over time in both groups and no statistically significant differences between groups in change in any of the parameters evaluation.
**Systematic Reviews**

Systematic reviews of the literature have been performed evaluating EECP for chronic stable angina. In 2010, Amin et al published a Cochrane review of major databases through 2008 on evidence of the effectiveness of EECP for chronic angina pectoris. The solitary RCT identified was the MUST-EECP trial. The authors of this review highlighted patient selection for this study. They comment that limiting the study population to patients with CCS class below IV diminishes the study’s generalizability to patients of interest, that is, patients with the most severe symptoms of chronic angina pectoris.

Also in 2010, Shah et al published a meta-analysis of prospective studies, not limited to RCTs, of EECP in stable angina in which CCS class was adequately reported before and after treatment. The MUST-EECP RCT was not included, as change in CCS class was not one of the reported outcomes. A total of 13 studies met these inclusion criteria (total N=949 patients). Overall, improvement of at least 1 level of angina class occurred in 86% of patients (95% confidence interval, 82% to 90%; p=0.008). No conclusions can be drawn from this analysis given the lack of randomization (comparison group) for most studies in this analysis.

In 2009, McKenna et al report on a systematic review and economic analysis of EECP for the treatment of stable angina and heart failure. Four studies (1 RCT, 3 nonrandomized comparative studies) comparing EECP treatment with no treatment in adults with chronic stable angina were included in the analysis. Similar to the previously reviewed Schechter et al study, “CCS classification improved with EECP but not with usual care, however statistical analysis of between group differences was not reported and, for CCS classification, the data were treated as continuous data which is inappropriate for this four-category classification.”

A 2016 systematic review and meta-analysis focused on the effect of EECP on intermediate measure of myocardial perfusion in patients with coronary artery disease. The systematic review included 6 studies reporting on myocardial perfusion or coronary flow outcomes published from 1992 to 2007, including 5 RCTs and 1 prospective, observational, blinded study. In pooled analysis, EECP was associated with increased myocardial perfusion in CAD patients (pooled weighted mean difference [WMD] -0.19, 95% CI, -0.38 to 0.00, P=0.049).

**Registry Studies**

Registry-based studies have been published that report on relatively large numbers of patients. In a registry-based study, 450 patients with left ventricular dysfunction (ejection fraction, ≤40) and refractory angina had 0.7 fewer emergency department visits and 0.8 fewer hospitalizations 6 months after treatment with EECP compared with the 6 months before EECP; 6-month data were available on only 81 patients. Drawing conclusions from this study is not possible due to lack of a comparison group.
Another registry-based study (the International Enhanced External Counterpulsation Patient [IECP] Registry) reported long-term (3-year) results on patients with chronic refractory angina for patients in this registry. (20) The registry enrolled 5000 patients from 99 U.S. and 9 international centers between 1999 and 2001. However, analysis was completed only for those centers who had at least 80% compliance with follow-up data submission; the study reported results on 1427 patients. In this selective group, 220 (15.4%) patients died, while 1061 (74.4%) patients completed their follow-up. Immediately post-EECP, the proportion of patients with severe angina (CCS class III/IV) were reduced from 89% to 25% (p<0.001). This was sustained in 74% of the patients during follow-up. More severe baseline angina and a history of heart failure or diabetes were independent predictors of unfavorable outcome. Again, the lack of a control group precludes drawing conclusions about this technology based on this study.

The IECP data have also been examined to determine the safety and efficacy of the use of this device in patients with peripheral arterial disease (PAD). PAD, while a common comorbidity of CAD, has been regarded as a relative contraindication to EECP due to concerns of compression on peripheral blood flow and a potentially greater risk of aortic rupture. Thakker et al compared registry data in patients with PAD to those without. (21) Based on a reduction of 1 or more CCS angina classes, patients with PAD had a similar rate of improvement (76.6% vs 79.0%, respectively; p=0.27), as did the group without PAD. Rates of hospitalization for all cardiac causes (6.1% vs 4.4%, respectively; p=0.17) and for unstable angina (5.4% vs 3.5%, respectively; p=0.25) were also similar between groups.

**Other Observational Studies**

Numerous individual observational studies have been detailed in previous reviews and are included in systematic reviews previously described. (4-6,9,17,22) For example, 2 prospective cohort studies (n=55 and n=61) with 1-year outcomes have been reported. (23,24) Improved CCS classification was the main reported outcome, which persisted for 1 year in 79% and 78% of patients in the respective studies. Both studies had higher rates of treatment completion and follow-up than the previously reported (registry) studies of long-term outcomes. These studies address the need for data regarding treatment durability.

**Section Summary: Chronic Stable Angina**

The data for use of EECP in chronic stable angina are insufficient to form conclusions on the efficacy of this treatment. The single randomized trial (MUST-EECP) that included relevant clinical outcomes reported a benefit on 1 of 4 main angina-related outcomes, and the magnitude of this benefit was of uncertain clinical significance. The RCTs that report on intermediate outcomes offer evidence on possible physiologic mechanisms underlying EECP treatment but do not themselves provide evidence of health outcome benefits. Observational studies, such as registry data and case series, offer little evidence on the efficacy of this procedure due to the variable natural history of angina, the multiple confounders of cardiac outcomes, and the potential for a placebo effect.
Heart Failure

The 510(k) approval of the Vasomedical devices states that objective measures such as peak oxygen consumption, exercise duration, and preload-adjusted maximal left ventricular (LV) power are improved following EECP therapy, as well as subjective measures of patient response to therapy, such as quality of life and functional ability measures. (25 23) However, no clinical details of these studies are provided in the U.S. Food and Drug Administration summary, and these data are not from controlled trials.

The 2005 TEC Assessment(11) included heart failure in the analysis and concluded the evidence supporting the role of EECP as an effective treatment for heart failure is lacking in both quantity and quality. A single randomized, multicenter study of EECP compared with usual care in 187 optimally medically managed patients with New York Heart Association (NYHA) functional class II/III heart failure with an ejection fraction of 35% or less of ischemic or idiopathic etiology, the Prospective Evaluation of EECP in Congestive Heart Failure (PEECH trial), was mostly inconclusive.(26) The design and methods of the PEECH trial were published by Feldman et al.(25) The results of the PEECH trial found statistically improved, but modest, changes in exercise duration and improved functional classification but not in quality of life or peak oxygen uptake (VO2peak).(26)

A subgroup analysis from the PEECH trial for heart failure was published.(2) It showed that subjects aged 65 years and older treated with EECP (n=41) were more likely to meet the exercise duration (35% vs 25% increased by ≥60 seconds) and VO2peak (30% vs 11% increased by ≥1.25 mL/kg/min) improvement thresholds compared with those undergoing sham treatment (n=45); there was no difference at 6 months in NYHA class. This poststudy analysis must be viewed as a preliminary result.

In 2015, Rampengan et al reported on a double-blinded randomized controlled trial evaluating EECP in patients with CHF treated in Indonesia.(27) Patients with NYHA functional class I/II symptomatic heart failure from a variety of causes were included. Patients were randomized to active EECP (n=56) or sham EECP (n=56), which involved the use of the EECP device at only 77 mmHg of pressure, vs the standard 300 mmHg. Analysis was per protocol, excluding 6 and 7 patients who dropped out of the active and sham groups, respectively. Post-intervention, active EECP group patients were more likely to have a 6 minute walk test (6MWT) distance of 300 m or greater (98.0% vs 32.7%, P<0.01). The change in 6MWT distance was greater (improved) for the active EECP patients than for the sham control patients (192.6 vs -9 m, P<0.05).

Similar to the evidence for EECP for angina, registry studies for heart failure provide relatively little insight into the comparative efficacy of EECP.(28-31) The single-arm study by Soran et al indicates that patients respond with some improvements, but the lack of a comparison arm precludes inference about the true effects of therapy.(32)
The previously described 2009 review by McKenna et al(16) included the single trial of EECP for heart failure available at the time the PEECH study.(26) The authors concluded that the studies did not provide firm evidence of the clinical effectiveness of EECP in refractory stable angina or in heart failure and that high-quality studies are required to investigate the benefits of EECP and whether these outweigh the common adverse effects.

**Section Summary: Heart Failure**
The evidence for the use of EECP in heart failure includes two RCTs that reports on clinical outcomes. One study reported modest improvements on some outcomes and no improvement on others. A second study reported improvements in the 6MWT, but has methodological limitations that limit conclusions that can be drawn. The observational studies add little to the evaluation of efficacy due to the variable natural history of heart failure, the multiple confounding variables for cardiac outcomes, and the potential for a placebo effect. Further high-quality RCTs are needed to determine whether EECP is a useful treatment for heart failure.

**Other Indications**
The use of EECP for other conditions associated with ischemia or vascular dysfunction has been investigated. In 2009, Fraser and Adams produced a Cochrane review on interventions for central retinal artery occlusion (CRAO).(33) One of the 2 RCTs identified compared hemodilution with EECP against hemodilution without further intervention. In this case, the EECP intervention was a single, 2-hour treatment. According to the reviewers, in this study (n=20), patients were randomized but not blinded; no sham treatment was given. Primary outcomes were Doppler flowmetry of retinal perfusion and visual acuity.(34) While acknowledging the relative safety of the technique, the authors remark: “The small size of the study[y], potential for bias and the lack of data on final vision means that we do not have convincing evidence at present to support the routine use of ... EECP in patients with CRAO.”

Published registry studies also demonstrated improvements in erectile function.(35) Erectile function was improved in a study of 120 men prospectively enrolled from 16 centers. Three of 5 domains of the International Index of Erectile Function were statistically improved with EECP treatment (erectile function, intercourse satisfaction, overall satisfaction), and the total score improved from 28 to 32, a statistically significant improvement.(35) The noncomparative design of this study makes it difficult to draw conclusions on treatment efficacy. This indication is added as investigational due to lack of adequate data on clinical outcomes. Preliminary studies from Asia are also reporting early results on use of EECP to the lower extremities in the treatment of acute ischemic stroke.(36) A 2012 Cochrane review of 2 RCTs of EECP in acute ischemic stroke(37) concluded that the methodologic quality of the studies was poor and reliable conclusions could not be reached from this evidence. Thus, this indication is considered as investigational due to inadequate evidence concerning impact on outcomes.

In 2016, Sardina et al reported on an RCT which randomized 30 patients with type 2 diabetes in a 2:1 ratio to EECP (n=20) or standard care for diabetes (n=10), and...
reported results out to 3(38) and 6 months.(39) At 6 months of follow up, patients in the EECP group had significant decreases over time in variety of biomarkers of advanced glycation end products, inflammation, and oxidative stress. At 6 months of follow up, the percent change in advanced glycation end products and receptor of advanced glycation end products differed significantly between groups (P<0.05).

**Ongoing and Unpublished Clinical Trials**
A search of ClinicalTrials.gov in July 2016 did not identify any ongoing or unpublished trials that would likely influence this review.

**Summary of Evidence**
For individuals who have chronic stable angina who receive enhanced external counterpulsation (EECP), the evidence includes randomized controlled trials (RCTs), observational studies, and systematic reviews. Relevant outcomes are overall survival, symptoms, morbid events, and functional outcomes. There is only 1 blinded randomized controlled trial (RCT) that includes clinical outcomes, and this trial reported benefit on only 1 of 4 main angina outcomes. Additional small RCTs report changes in physiologic measures associated with EECP but do not provide relevant evidence on clinical efficacy. Because of the variable natural history of angina, the multiple confounding variables for cardiac outcomes, and the potential for a placebo effect, RCT evidence is needed. Therefore, observational studies, including registry studies with large numbers of patients, add little to determinations of efficacy. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals who have heart failure who receive EECP, the evidence includes RCTs, observational studies, and systematic reviews. Relevant outcomes are overall survival, symptoms, morbid events, and functional outcomes. One RCT that reported on clinical outcomes reported a modest benefit with EECP on some outcomes and no benefit on others. A second RCT reported improvements on the 6 minute walk test with EECP, but has methodological limitations that limit conclusions that can be drawn. The observational studies on EECP in heart failure have limited ability to inform the evidence on EECP due to the multiple confounding variables for cardiac outcomes and the potential for a placebo effect. The evidence is insufficient to determine the effects of the technology on health outcomes.

**SUPPLEMENTAL INFORMATION**
**Clinical Input Received From Physician Specialty Societies and Academic Medical Centers**
While the various physician specialty societies and academic medical centers may collaborate with and make recommendations during this process, through the provision of appropriate reviewers, input received does not represent an endorsement or position statement by the physician specialty societies or academic medical centers, unless otherwise noted.
In response to requests, input was received from 3 academic medical centers while this policy was under review, one during review in April 2008, one during review in October 2008, and one during review in 2009. Reviewers agreed with the conclusion that this was investigational. Some reviewers commented about potential use in those with angina not amenable to surgical interventions.

**Practice Guidelines and Position Statements**

The 2012 American College of Cardiology/American Heart Association (ACC/AHA) guidelines on the management of patients with stable ischemic heart disease indicate EECP “may be considered for relief of refractory angina.” This recommendation is based on Class IIb, Level of Evidence: B, which indicates the efficacy of the intervention is not well established and further studies would be helpful.(40)

The 2013 ACC/AHA guidelines on the management of heart failure do not address EECP.(41)

In 2014, ACC/AHA issued a Focused Update on the 2012 guideline on the diagnosis and management of patients with stable ischemic heart disease in which they specifically reviewed their recommendation on EECP. Based on their review, the recommendation on EECP remains unchanged from the 2012 guideline.

**U.S. Preventive Services Task Force Recommendations**

Not applicable.

**Medicare National Coverage**

Medicare has published a national coverage decision (NCD) regarding EECP that mandates coverage for the following indications(42):

“Coverage is provided for the use of EECP for patients who have been diagnosed with disabling angina who, in the opinion of a cardiologist or cardiothoracic surgeon, are not readily amenable to surgical intervention, such as percutaneous transluminal coronary angioplasty or cardiac bypass because: 1) Their condition is inoperable, or at high risk of operative complications or post-operative failure; 2) Their coronary anatomy is not readily amendable to such procedures; or 3) They have co-morbid states which create excessive risk.”

Medicare’s coverage policy also notes that while the U.S. Food and Drug Administration has cleared EECP “for use in treating a variety of cardiac conditions, including stable or unstable angina pectoris, acute myocardial infarction and cardiogenic shock, the use of this device to treat cardiac conditions other than stable angina pectoris is not covered....”

This Medicare NCD differs from the BCBSA determination of medical necessity. The discrepancy primarily arises from different interpretations of the MUST-EECP trial. In the original Centers for Medicare and Medicaid Services NCD issued in November 1999,(43) the conclusion was that, based on the results of MUST-EECP,
EECP was reasonable and necessary for patients with severe angina refractory to medical and/or surgical intervention. Subsequent reanalyses of this decision in 2001 and 2006(42) did not result in any changes to the coverage position. In contrast, a TEC Assessment performed in 1999 concluded that evidence from the MUST-EECP trial was not sufficient to permit conclusions on the impact of the technology (see the Rationale section for TEC conclusions on the MUST-EECP trial). Subsequent TEC Assessments in 2002 and 2005,(1) which considered the MUST-EECP trial together with additional evidence, also concluded that the evidence was not sufficient to permit conclusions.

</table>
ankle/brachial indices at distal posterior tibial and anterior tibial/dorsalis pedis arteries with, transcutaneous oxygen tension measurement at 1-2 levels)

G0166  External counterpulsation, per treatment session

ICD-10 Codes
I20.1-  Angina pectoris code range (I20.0 is unstable angina pectoris)
I20.9
I50.1-  Heart failure code range
I50.9

Additional Policy Key Words
N/A

Policy Implementation/Update Information
10/1/03  New policy added to the surgery section.
10/1/04  No policy statement changes.
10/1/05  No policy statement changes.
10/1/06  No policy statement changes.
10/1/07  No policy statement changes. Title updated from “Enhanced External Counterpulsation” to “Enhanced External Counterpulsation (EECP) for Chronic Stable Angina or Congestive Heart Failure.”
10/1/08  Policy statement revised to include erectile dysfunction as an investigational indication.
10/1/09  Policy statement revised to include ischemic stroke as an investigational indication.
10/1/10  No policy statement changes.
10/1/11  No policy statement changes.
10/1/12  No policy statement changes.
10/1/13  Title of policy changed to indicate it applies to more indications than only chronic stable angina and heart failure. Added to the description. No policy statement changes.
10/1/14  No policy statement changes.
10/1/15  No policy statement changes.
10/1/16  No policy statement changes.
10/1/17  No policy statement changes.
