Intraocular Radiotherapy for Age-Related Macular Degeneration

**Policy Number:** 9.03.20  
**Origination:** 9/2008  
**Last Review:** 9/2016  
**Next Review:** 9/2017

**Policy**
Blue Cross and Blue Shield of Kansas City (Blue KC) will not provide coverage for intraocular radiation therapy for age-related macular degeneration. This is considered investigational.

**When Policy Topic is covered**
Not Applicable

**When Policy Topic is not covered**
Intraocular placement of a radiation source (brachytherapy) for the treatment of choroidal neovascularization is considered **investigational**.

Proton beam therapy for the treatment of choroidal neovascularization is considered **investigational**.

Stereotactic radiation therapy for the treatment of choroidal neovascularization is considered **investigational**.

**Description of Procedure or Service**

</table>
Intraocular radiation, including brachytherapy, proton beam therapy, and stereotactic radiotherapy, are being evaluated to treat choroidal neovascularization (CNV) associated with age-related macular degeneration (AMD).

The evidence for brachytherapy in individuals who have CNV due to AMD includes a randomized controlled trial (RCT) of brachytherapy plus vascular endothelial growth factor (VEGF) versus VEGF monotherapy, as well as phase 1/2 trials and case series on the use of brachytherapy. Relevant outcomes are change in disease status, morbid events, functional outcomes, quality of life, medication use, and treatment-related morbidity. The RCT showed that brachytherapy did not attain noninferiority for visual outcomes and was associated with a higher proportion of adverse events. The evidence is insufficient to determine the effects of the technology on health outcomes.

The evidence for proton beam therapy in individuals who have CNV due to AMD includes a randomized, prospective, sham-controlled trial and a pilot study. Relevant outcomes are change in disease status, morbid events, functional outcomes, quality of life, medication use, and treatment-related morbidity. Recruitment into the RCT was halted for ethical concerns and available results did not show statistically significant stabilization of visual acuity. The evidence is insufficient to determine the effects of the technology on health outcomes.

The evidence for stereotactic radiotherapy in individuals who have CNV due to AMD includes an RCT with sham control. Relevant outcomes are change in disease status, morbid events, functional outcomes, quality of life, medication use, and treatment-related morbidity. The RCT showed a reduction in the number of VEGF treatments at 12- and 24-month intervals, but no significant differences versus controls in changes in visual acuity. The evidence is insufficient to determine the effects of the technology on health outcomes.

Background
Age-related macular degeneration (AMD) is the leading cause of legal blindness in individuals older than age 60 in developed nations. AMD is characterized in its earliest stages by minimal visual impairment and the presence of large drusen and other pigmentary abnormalities on ophthalmoscopic examination. Two distinctive forms of degeneration may be observed. The first, called the atrophic or areolar or dry form, evolves slowly. Atrophic AMD is the most common form of degeneration and may be a precursor of the more visually impairing exudative neovascular form, also referred to as disciform or wet AMD. The wet form is distinguished from the atrophic form by the development of choroidal neovascularization (CNV) and
serous or hemorrhagic detachment of the retinal pigment epithelium. Risk of developing severe irreversible loss of vision is greatly increased by the presence of CNV.

Usual care for neovascular AMD may include photodynamic therapy or intravitreal injections of agents that target vascular endothelial growth factor, which may necessitate repeated intravitreal injections. Therefore, alternative treatments, such as intraocular radiation, including brachytherapy, proton beam therapy (PBT), and stereotactic radiotherapy, are being investigated.

The NeoVista Epi-Rad90 Ophthalmic System, a brachytherapy device, treats CNV by delivery of focal radiation to a subfoveal choroidal neovascular lesion. Using a standard vitrectomy procedure, the cannula tip of a handheld (pipette-like) surgical device is inserted into the vitreous cavity and positioned under visual guidance over the target lesion. The radiation source (strontium-90) is advanced down the cannula until it reaches the tip, which is then held in place over the lesion for a “prescribed” time to deliver focused radiation. The system is designed to deliver a 1-time peak dose of beta particle energy (24 gray) for a target area 3 mm in depth and up to 5.4 mm in diameter. This dose is believed to be below that toxic to the retina and optic nerve. Radiation exposure outside of the target area is expected to be minimal.

PBT is a type of external radiation that uses charged atomic particles (protons or helium ions) to target a given area. PBT differs from conventional electromagnetic (photon) radiotherapy in that, with PBT, there is less scatter as the particle beams pass through tissue to deposit ionizing energy at precise depths (Bragg peak). The theoretical advantage of PBT over photon therapy is the ability to deliver higher radiation doses to the target without harm to adjacent normal tissue.

Stereotactic radiotherapy is a nonsurgical procedure performed in an office setting. It uses a robotically controlled device to deliver radiation beams through the inferior sclera to overlap at the macula.

**Other Treatments for AMD**

Other available therapeutic options for AMD not addressed in this evidence review include photodynamic therapy (evidence review 9.03.08) and vascular endothelial growth factor antagonists or angiostatics.

For those whose visual loss impairs their ability to perform daily tasks, low-vision rehabilitative services offer resources to compensate for deficits.

**Regulatory Status**

No devices are specifically approved by the U.S. Food and Drug Administration (FDA) for intraocular radiation. An investigational device exemption was granted by FDA for a phase 3 multicenter trial of the EPI-RAD90™ (now known as Vidion Anti-Neovascular Epimacular Brachytherapy [EMBT] System; NeoVista) to provide data for a device application to FDA. This is a category B procedure.
**Rationale**

This evidence review was created in 2008 and has been periodically updated with literature searches using the MEDLINE database. The most recent literature review was performed through February 2, 2016.

A search of MEDLINE when this evidence review was created did not identify any peer-reviewed publications on epiretinal radiation. The original search did identify older randomized trials using external beam radiotherapy for age-related macular degeneration (AMD)-associated choroidal neovascularization (CNV). Little to no benefit in visual acuity was observed following repeated single treatments of 2 gray (Gy) to a total of 12 to 20 Gy.¹ ²

**Brachytherapy**

CABERNET (NCT00454389) is a phase 3 multicenter, randomized controlled trial (RCT) that enrolled 494 subjects with AMD-related wet CNV from 42 sites.³ ⁴ The safety and efficacy of epiretinal radiotherapy combined with 2 loading injections of ranibizumab (Lucentis®) was compared to ranibizumab monotherapy (2 loading doses and then quarterly). Patients in both arms of the study could receive monthly treatment with ranibizumab as needed. At 24 months, 77% of the patients in the EPI-RAD90 group lost fewer than 15 letters compared with 90% in the control group. This result did not meet the prespecified noninferiority margin. EPI-RAD90 treatment also did not meet the superiority end point, which was the proportion of participants gaining more than 15 letters (16% vs 26% for the ranibizumab group). The most common serious adverse event was cataract surgery (known to be associated with vitrectomy), which occurred in 40% of the EPI-RAD90 group compared with 11% of the ranibizumab monotherapy group. Mild radiation retinopathy occurred in 3% of the patients who received EPI-RAD90 treatment. This study did not support the use of epiretinal radiotherapy.

Twelve- and 24-month results from the multicenter MERITAGE study (NCT00809419) were reported between 2012 and 2014.⁵ ⁷ MERITAGE was a phase 1/2 study of EPI-RAD90 for the treatment of subfoveal CNV associated with wet AMD in patients requiring continued antivascular endothelial growth factor (anti-VEGF) therapy to maintain an adequate response. Following a single 24-Gy dose, the 53 patients in the study received retreatment with ranibizumab administered monthly (as needed). In the 12 months before the study, participants received 0.45 injections per month. At the 12-month follow-up, 81% of patients maintained stable vision (loss of <15 letters) with a mean of 3.49 anti-VEGF injections (0.29 per month). Over 24 months, the durability of the application diminished, with 68% of patients maintaining stable vision at a mean of 8.7 anti-VEGF injections (0.72 per month).

Three publications from 2 studies have been reported by Avila et al on epiretinal radiation using the EPI-RAD90 System.⁸ ¹⁰ One report described 12-month safety and visual acuity results from a feasibility study in 34 treatment-naive patients from Turkey, Mexico, and Brazil, recruited between February 2005 and February 2006.⁸ The second report described 12-month safety and visual acuity results from
24-Gy epiretinal radiation combined with bevacizumab in 34 treatment-naive patients enrolled between June 2006 and April 2007. Adverse events related to the device or procedure included subretinal hemorrhage (n=1), retinal tear (n=1), subretinal fibrosis (n=2), epiretinal membrane (n=1), and cataract (n=6/24; 24 patients were phakic at baseline). All occurrences of cataracts were deemed to be related to the vitrectomy procedure. Two- and 3-year results from this trial were published in 2012. All 34 subjects were followed for 24 months; 1 site that enrolled 19 patients agreed to reconsent and follow patients for 3 years. On average, the cohort followed for 36 months received 3.0 bevacizumab injections. Twelve (50%) of the 24 phakic patients developed cataracts, and 4 had phacoemulsification with intraocular lens implantation. Mean change in visual acuity at 36 months was +3.9 letters. Seven (54%) of 13 phakic patients developed cataracts, and 4 had phacoemulsification with intraocular lens implantation. One case of nonproliferative radiation retinopathy was observed at 36 months.

Proton Beam Therapy
In 2012, Park et al reported 12- to 36-month follow-up of a pilot study of ranibizumab combined with proton beam therapy (PBT) for AMD. Six eyes (6 patients) were treated with 4 monthly ranibizumab plus 24-Gy proton beam treatments, followed by ranibizumab if needed. No radiation retinopathy was observed at follow-up.

In 2002, Ciulla et al reported results from a randomized, prospective, sham-controlled, double-masked treatment trial that examined the effect of PBT on subfoveal choroidal neovascular membranes associated with AMD. Thirty-seven subjects were randomly assigned to 16-Gy proton irradiation delivered in 2 fractions 24 hours apart or to sham control treatment. Recruitment was halted at 37 subjects for ethical reasons related to randomization to sham treatment when U.S. Food and Drug Administration approval of Visudyne® (a light-activated drug used with photodynamic therapy) was anticipated. PBT was associated with a trend toward stabilization of visual acuity, but this association was not statistically significant.

Stereotactic Radiotherapy
INTREPID was a randomized, sham-controlled, double-masked trial with 230 patients that assessed the efficacy and safety of stereotactic radiotherapy (SRT) to treat neovascular AMD. The primary outcome measure was the number of ranibizumab injections needed over 52 weeks. Both SRT and sham-control patients received ranibizumab as needed. After 1 year, treatment with 16- or 24-Gy SRT reduced the number of ranibizumab treatments (median of 2 vs 3.5 for sham controls) with no significant differences from controls in changes in visual acuity over the 1-year of follow-up. No safety concerns were identified in the first 12 months.

In 2015, year 2 safety and efficacy results from the INTREPID trial were published. Participants received 16- or 24- Gy SRT or sham SRT and ranibizumab for 12 months, with bevacizumab or ranibizumab thereafter as needed. At year 2,
the 16- and 24-Gy arms received fewer as needed bevacizumab (mean, 4.5, p=0.008) or ranibizumab (mean 5.4, p=0.09) treatments compared with sham (mean, 6.6). Changes in mean best-corrected visual acuity were -10.0, -7.5, and -6.7 letters, respectively, with 68%, 75%, and 79% losing fewer than 15 letters, respectively. Differences for visual acuity were not statistically significant.

Microvascular abnormalities were detected in 6 control eyes and 29 SRT eyes, of which 18 were attributed to radiation, with only 2 possibly affecting vision. The authors concluded that a single dose of SRT significantly reduced intravitreal injections over 2 years, and that, although radiotherapy can induce microvascular changes, only in 1% of eyes did this seem to affect vision.

**Ongoing and Unpublished Clinical Trials**

Some currently unpublished trials that might influence this review are listed in Table 1.

**Summary of Evidence**

The evidence for brachytherapy in individuals who have choroidal neovascularization (CNV) due to age-related macular degeneration (AMD) includes a randomized controlled trial (RCT) of brachytherapy versus vascular endothelial growth factor (VEGF) versus VEGF monotherapy, as well as phase 1/2 trials and case series on the use of brachytherapy. Relevant outcomes are change in disease status, morbid events, functional outcomes, quality of life, medication use, and treatment-related morbidity. The RCT showed that brachytherapy did not attain noninferiority for visual outcomes and was associated with a higher proportion of adverse events. The evidence is insufficient to determine the effects of the technology on health outcomes.

The evidence for proton beam therapy in individuals who have CNV due to AMD includes a randomized, prospective, sham-controlled trial and a pilot study. Relevant outcomes are change in disease status, morbid events, functional
outcomes, quality of life, medication use, and treatment-related morbidity. Recruitment into the RCT was halted for ethical concerns and available results did not show statistically significant stabilization of visual acuity. The evidence is insufficient to determine the effects of the technology on health outcomes.

The evidence for stereotactic radiotherapy in individuals who have CNV due to AMD includes an RCT with sham control. Relevant outcomes are change in disease status, morbid events, functional outcomes, quality of life, medication use, and treatment-related morbidity. The RCT showed a reduction in the number of VEGF treatments at 12- and 24-month intervals, but no significant differences versus controls in changes in visual acuity. The evidence is insufficient to determine the effects of the technology on health outcomes.

Supplemental Information

Practice Guidelines and Position Statements
The 2011 guidance from the U.K.'s National Institute for Health and Clinical Excellence (NICE) states that current evidence on the efficacy of epiretinal brachytherapy for wet AMD is "inadequate and limited to small numbers of patients." For safety, "vitrectomy has well-recognised complications and there is a possibility of subsequent radiation retinopathy." NICE concluded that wet AMD should only be used for "research."15

U.S. Preventive Services Task Force Recommendations
Not applicable.

Medicare National Coverage
There is no national coverage determination (NCD). In the absence of an NCD, coverage decisions are left to the discretion of local Medicare carriers.

CPT code 0190T is to be used in conjunction with 67036 (Vitrectomy, mechanical, pars plana approach).

CPT code 0190T differs from code 67218 (destruction of localized lesion of the retina (e.g., macular edema, tumors), one or more sessions; radiation by implantation of source) because the radiation source is not implanted.
