Balloon Ostial Dilation for Treatment of Chronic Rhinosinusitis

Policy Number: 7.01.105
Origination: 3/2007
Last Review: 3/2019
Next Review: 9/2019

Policy
Blue Cross and Blue Shield of Kansas City (Blue KC) will not provide coverage for balloon rhinosinusitis. This is considered investigational.

When Policy Topic is covered
Not Applicable

When Policy Topic is not covered
Use of a catheter-based inflatable device (balloon ostial dilation) in the treatment of rhinosinusitis is considered investigational.

Considerations
There are specific category I CPT codes for these procedures (31295-31298). These codes may be used to describe balloon sinus ostial dilation when no other surgical intervention has been performed on the same sinus site.

This procedure might also be coded as an unlisted sinus procedure (31299). It could be submitted alone or with other nasal/sinus endoscopy codes.

If balloon sinus ostial dilation is performed with cutting tools such as curettes and forceps, the procedure might use the CPT codes for nasal/sinus endoscopy with maxillary antrostomy (31256), nasal/sinus endoscopy with frontal sinus exploration (31276), or nasal/sinus endoscopy with sphenoidectomy (31287). Plans should be aware of these possibilities. In those instances, the balloon dilation would be considered inclusive/incidental to the procedure.

In the Medicare outpatient hospital setting, HCPCS code C1726 may be used for the device.

Balloon ostial dilation (also known as balloon sinuplasty™) is proposed as an alternative to traditional endoscopic sinus surgery (ESS) for patients with chronic sinusitis who fail medical management. The procedure involves placing a balloon in the sinus ostium and inflating the balloon to stretch the opening. It can be performed as a stand-alone procedure or as an adjunctive procedure to functional endoscopic sinus surgery (FESS).

For individuals with chronic rhinosinusitis who receive balloon ostial dilation as a stand-alone procedure includes the evidence includes systematic reviews, including a Cochrane review and a Blue Cross and Blue Shield Association TEC Assessment and RCTs. Relevant outcomes are symptoms, change in disease status, quality of life, and treatment-related morbidity. The available systematic reviews have concluded that, although nonrandomized evidence suggests that balloon ostial dilation has similar outcomes to FESS. Since the publication of the systematic reviews, an additional RCT has been published (the REMODEL study). It included 105 patients, reporting short-term improvement in symptoms that are similar to those seen with FESS and potential advantages for balloon ostial dilation on postoperative recovery time and pain medication use. Limitations of the REMODEL study include the unblinded design, lack of blinded outcome assessment across the range of outcome measures, and differential dropout between groups. Other trials provide limited additional evidence. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals with chronic rhinosinusitis who receive balloon ostial dilation as an adjunct to FESS, the evidence includes 2 small RCTs. Relevant outcomes are symptoms, change in disease status, quality of life, and treatment-related morbidity. The 2 available RCTs did not report significant clinically meaningful benefits associated with the addition of FESS. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Background**

**Chronic Rhinosinusitis**

Chronic rhinosinusitis (CRS) is characterized by purulent nasal discharge, usually without fever, that persists for weeks to months. Symptoms of congestion often accompany the nasal discharge. There also may be mild pain and/or headache. Thickening of mucosa may restrict or close natural openings between sinuses.
cavities and the nasal fossae, although symptoms vary considerably because of
the location and shape of these sinus ostia.

Estimates have suggested approximately 30 million individuals in the United
States suffer from CRS. Most cases are treated with medical therapy, but surgical
drainage is an option for patients who fail to respond to medical therapy.
Functional endoscopic sinus surgery (FESS) has become an important aspect for
surgical management of chronic sinusitis, although evidence from randomized
controlled trials (RCTs) is limited. For this procedure, a fiberoptic nasal endoscope
is used to visualize the sinus ostia, and any obstruction found is corrected. This
procedure restores patency and allows air and mucous transport through the
natural ostium. Approximately 350,000 FESS procedures are done each year in the
United States for CRS.

Treatment
A newer procedure, balloon ostial dilatation can be used as an alternative to FESS
or as an adjunct to FESS for those with CRS. The goal of this technique, when
used as an alternative to FESS, is to improve sinus drainage using a less invasive
approach. When used as an adjunct to FESS, it is intended to facilitate and/or
increase access to the sinuses. The procedure involves placing a guidewire in the
sinus ostium, advancing a balloon over the guidewire, and then stretching the
opening by inflating the balloon. The guidewire location is confirmed with
fluoroscopy or with direct transillumination of the targeted sinus cavity. General
anesthesia may be needed for this procedure to minimize patient movement.

The maxillary sinus creates a unique challenge. The maxillary ostia, located within
the ethmoid infundibulum, often cannot be accessed transnasally without excising
a portion of the uncinate process. An alternative approach to the maxillary ostia is
through the sinus, via the canine fossa. A guidewire can be advanced from within
the maxillary sinus to the nasal fossa. The dilating balloon can enlarge the ostia
while deflecting the uncinate process.

Outcomes
To quantify the severity of CRS and to assess treatment response, various
outcomes measures can be used, including patient-reported quality of life (QOL)
measures, radiologic scores, and endoscopic grading.

The Lund-Mackay scoring system uses radiologist-rated information derived from
computed tomography scans regarding opacification of the sinus cavities,
generating a score from 0 to 12.1,2

Disease-specific patient-reported QOL scores have been used. Commonly used is
the Sino-Nasal Outcome Test–20 (SNOT-20), which is a validated questionnaire for
which patients complete 20 symptom questions on a categoric scale (0 [no bother]
to 5 [worst symptoms can be]). Average rankings can be reported over all 20
symptoms, as well as by 4 subclassified symptom domains. The SNOT-22, a
variation of the SNOT-20, includes 2 additional questions (“nasal obstruction” and
“loss of smell and taste”). The minimal clinically important difference for the SNOT-22 has been estimated to be 8.9 points.\(^3\)

Additionally, QOL has been reported using overall health-related QOL scores, such as the 36-Item Short-Form Health Survey. That tool includes 8 scaled scores on various health domains, which are transformed into a 0-to-100 scale (100 corresponding to best health).

**Regulatory Status**

In March 2008, the Relieva™ Sinus Balloon Catheter (Acclarent, Menlo Park, CA) was cleared for marketing by the U.S. Food and Drug Administration (FDA) through the 510(k) process. FDA determined that this device was substantially equivalent to existing devices for use in dilating the sinus ostia and paranasal spaces in adults and maxillary sinus spaces in children. Subsequent devices developed by Acclarent have also been cleared by FDA through the 510(k) process. They include the Relieva Spin Sinus Dilation System® (cleared in August 2011) and the Relieva Seeker Balloon Sinuplasty System® (cleared in November 2012).

In June 2008, the FinESS™ Sinus Treatment (Entellus Medical, Maple Grove, MN) was cleared for marketing by FDA through the 510(k) process. The indication noted is to access and treat the maxillary ostia/ethmoid infundibulum in adults using a transantral approach (FDA product code: EOB). The bony sinus outflow tracts are remodeled by balloon displacement of adjacent bone and paranasal sinus structures. Two other balloon sinus ostial dilation devices, the ENTrigue® Sinus Dilation System (ENTrique Surgical, acquired by ArthroCare and more recently by Smith and Nephew), and the XprESS™ Multi-Sinus Dilation Tool, also received 510(k) clearance in August 2012.

In 2013, a sinus dilation system (Medtronic Xomed, Jacksonville, FL), later named the NuVent™ EM Balloon Sinus Dilation System, was cleared for marketing by FDA through the 510(k) process for use in conjunction with a Medtronic computer-assisted surgery system when surgical navigation or image-guided surgery may be necessary to locate and move tissue, bone, or cartilaginous tissue surrounding the drainage pathways of the frontal, maxillary, or sphenoid sinuses.

Also in 2013, a sinus dilation system (ArthroCare, San Antonio, TX, a division of Smith and Nephew), later named the Ventera™ Sinus Dilation System, was cleared for marketing through the 510(k) process to access and treat the frontal recesses, sphenoid sinus ostia, and maxillary ostia/ethmoid infundibula in adults using a transnasal approach.

**Rationale**

This evidence review was created in July 2006 and has been updated regularly with searches of the MEDLINE database. The most recent literature update was performed through December 11, 2017.
Evidence reviews assess the clinical evidence to determine whether the use of a technology improves the net health outcome. Broadly defined, health outcomes are length of life, quality of life, and ability to function—including benefits and harms. Every clinical condition has specific outcomes that are important to patients and to managing the course of that condition. Validated outcome measures are necessary to ascertain whether a condition improves or worsens; and whether the magnitude of that change is clinically significant. The net health outcome is a balance of benefits and harms.

To assess whether the evidence is sufficient to draw conclusions about the net health outcome of a technology, 2 domains are examined: the relevance and the quality and credibility. To be relevant, studies must represent one or more intended clinical use of the technology in the intended population and compare an effective and appropriate alternative at a comparable intensity. For some conditions, the alternative will be supportive care or surveillance. The quality and credibility of the evidence depend on study design and conduct, minimizing bias and confounding that can generate incorrect findings. The randomized controlled trial (RCT) is preferred to assess efficacy; however, in some circumstances, nonrandomized studies may be adequate. RCTs are rarely large enough or long enough to capture less common adverse events and long-term effects. Other types of studies can be used for these purposes and to assess generalizability to broader clinical populations and settings of clinical practice.

Balloon sinus ostial dilation can be performed as a stand-alone procedure or as an adjunct to functional endoscopic sinus surgery (FESS). When performed in combination with FESS, it is sometimes referred to as a hybrid procedure because there are elements of both balloon sinus ostial dilation and FESS.

The primary outcome measures relevant for the treatment of chronic rhinosinusitis (CRS) are patient-reported symptoms and quality of life. Studies should predefine responder criteria for whatever outcome measures are used and assess between-group differences in the proportion of patients considered responders. Examiner evaluation of the nasal and sinus appearance and polyp size may provide some information about treatment outcomes, but these evaluations are limited by the lack of universally accepted standards.

The literature consists of a few small RCTs, a small number of non-RCTs, and a larger number of single-arm case series, most of which are retrospective. This evidence is reviewed next, with emphasis on the available controlled trials, in 2 categories: (1) balloon ostial dilation as a stand-alone procedure and (2) balloon ostial dilation as an adjunct to FESS.

**Balloon Ostial Dilation as a Stand-Alone or Adjunct Procedure**

This section discusses both indications—balloon ostial dilation as a stand-alone and as an adjunct procedure—because the systematic reviews discuss both approaches or do not distinguish sufficiently between one and the other procedure.
Systematic Reviews
A 2012 TEC Assessment on balloon ostial dilation for treatment of CRS reviewed evidence from 1 RCT, 3 nonrandomized comparative studies, and 9 case series. The TEC Assessment concluded that the evidence was insufficient to determine the effect of the technology on health outcomes. One RCT comparing balloon sinus ostial dilation with FESS was inadequately powered and did not evaluate differences in outcomes between treatments. While most nonrandomized comparative studies of balloon sinus ostial dilation and FESS showed no difference in health outcomes between both treatments, confounding factors might have biased the comparisons. Several case series showed improvement in symptoms of rhinosinusitis over baseline measures, and such improvement appeared durable up to 2 years. Case series did not allow conclusions on the comparative efficacy of balloon sinus ostial dilation to FESS.

A Cochrane review (2011) assessed the literature on balloon sinus ostial dilation for CRS. Reviewers concentrated on RCTs, and included the Plaza et al (2011) RCT as the sole controlled trial meeting selection criteria. Reviewers rated this trial as having a low risk of bias for most parameters, but a high risk of bias in reporting outcomes. They noted that symptom scores were not presented systematically and that details of statistical testing were not reported. Reviewers’ overall conclusion was that there is no convincing evidence supporting the use of balloon sinus ostial dilation in CRS.

Levy et al (2016) reported on a systematic review and meta-analysis of studies of paranasal balloon ostial dilation for CRS. Reviewers included 17 studies, with 3 RCTs (Achar et al [2012], Bikhazi et al [2014], Cutler et al [2013]). Two RCTs reported on change score differences for the Sino-Nasal Outcome Test–20 (SNOT-20) between patients treated with balloon ostial dilation and with FESS (n=110; standard mean difference, -0.42; 95% confidence interval [CI], -1.39 to 0.55; $I^2=76\%$). There were improvements in SNOT-20 scores and sinus opacification after balloon ostial dilation.

Batra et al (2011) performed a comprehensive review of the literature on balloon catheter technology in rhinology. They included observational cohort studies that provided relatively less evidence about the efficacy of balloon ostial dilation. Reviewers concluded that prospective RCTs comparing FESS with balloon catheter technology were needed.

Balloon Ostial Dilation as a Stand-Alone Procedure Vs FESS Alone
Randomized Controlled Trials

REMODEL Trial
REMODEL was an industry-sponsored RCT (Cutler et al [2013]) that compared balloon ostial dilation as a stand-alone procedure with FESS. A total of 105 patients with recurrent acute sinusitis or chronic sinusitis and failure of medical therapy were randomized to balloon ostial dilation or FESS. Balloon ostial dilation was performed with the Entellus device, which is labeled for a transantral
approach. FESS consisted of maxillary antrostomy and uncinectomy with or without anterior ethmoidectomy. Thirteen patients withdrew consent before treatment, 11 (21%) in the FESS group and 2 (4%) in the balloon ostial dilation group. The primary outcomes were the change in SNOT-20 scores at 6-month follow-up and mean number of postoperative débridements. Secondary outcomes included recovery time, complication rates, and rates of revision surgery. Both superiority and noninferiority analyses were performed on these outcomes.

Ninety-one patients were available at 6-month follow-up. The improvement in the SNOT-20 score was 1.67 in the balloon dilation group and 1.60 in the FESS arm ($p=0.001$ for noninferiority). Postoperative débridements were more common in the FESS group (1.2) than in the balloon dilation group (0.1; $p<0.001$ for superiority in the FESS arm). Patients in the balloon dilation arm returned to normal daily activities faster (1.6 days vs 4.8 days, $p=0.002$ for superiority) and required fewer days of prescription pain medications (0.9 days vs 2.8 days, $p=0.002$ for superiority) with balloon dilation. There were no major complications in either group, and 1 patient in each group required revision surgery.

Bikhazi et al (2014) reported 1-year follow-up from the REMODEL trial. Eighty-nine (96.7%) subjects were available at 1 year. Improvement in the SNOT-20 score was 1.64 in the balloon dilation arm and 1.65 in the FESS arm ($p<0.001$ for noninferiority). During the year postprocedure, both groups had fewer self-reported rhinosinusitis episodes (reduction in episodes, 4.2 in the balloon arm vs 3.5 in the FESS arm; $p<0.001$).

Chandra et al (2016) reported on results up to 2 years postprocedure for subjects in the REMODEL trial, along with an additional 30 subjects treated with FESS or in-office balloon sinus dilation patients. Follow-up data were available for 130, 66, and 25 patients at 12, 18, and 24 months, respectively. Details about group-specific treatment received and loss to follow-up were not reported for the additional 30 patients not included in the REMODEL trial. The balloon sinus dilation group required 0.2 débridements per patient compared with 1.0 per patient in the FESS group ($p<0.001$). Mean change in SNOT-20 score from baseline to 12-month follow-up was -1.59 ($p<0.001$) and -1.60 ($p<0.001$) for the balloon sinus dilation and FESS groups, respectively, which was considered clinically significant. These changes were maintained at 24 months. At 18 months, overall revision rates were 2.7% in the balloon dilation group and 6.9% in the FESS group. In addition to the longer term results of the REMODEL trial, this article included a meta-analysis of the REMODEL balloon dilation–treated patients and data from 5 manufacturer-sponsored trials, three of which had previously been reported in peer-reviewed form (BREATHE: Stankiewicz et al [2010], Stankiewicz et al [2012]; RELIEF: Levine et al [2013]; XprESS Transnasal Maxillary Multi-Sinus: Gould et al [2014]). Across the 6 studies, 846 patients were treated with balloon sinus dilation, including 121 not described in prior publications. In a random-effects model, overall mean and subscale scores for the SNOT-20 improved compared with baseline at every follow-up time point.
**Additional RCTs**

Bizaki et al (2014) reported on results from an RCT that compared balloon ostial dilation with FESS among patients with symptomatic chronic or recurrent rhinosinusitis. The trial enrolled 46 subjects, 4 of whom withdrew; the analysis included 42 patients (n=21 in each group; statistical power calculations reported). Both groups demonstrated significant improvements in SNOT-22 scores from baseline to postprocedure. There were no differences in change in total SNOT-22 scores between groups at 3 months postprocedure. As a 2016 follow-up publication, trialists reported on nasal airway resistance and sinus symptoms between FESS- and balloon ostial dilation–treated groups. For this analysis, 62 patients were included (32 from the FESS group, 30 from the balloon dilation group). Patients in the balloon ostial dilation group had significant improvements in nasal volume from pre- to postoperative measurements, but there were no significant differences between groups pre- or postoperatively in nasal volume.

Another RCT by Bizaki et al (2016) compared balloon ostial dilation with FESS, with a focus on mucociliary clearance. While conducted at the same institution as the previously reported Bizaki RCT, this RCT did not specify whether it was conducted in the same set of patients. This trial enrolled 36 patients who were randomized to balloon ostial dilation (n=17) or to FESS (n=19); 7 patients dropped out (3 in the FESS group, 4 in the balloon dilation group) and were not included in analyses. SNOT-22 scores improved in both groups from pre- to postoperative analyses. However, changes in total SNOT-22 scores did not differ significantly between groups. There were no significant changes in mucociliary clearance before and after either treatment nor was there a significant between-group difference in mucociliary clearance.

Marzetti et al (2014) reported on results from a small RCT that compared balloon ostial dilation using an unspecified device (or devices) with FESS in the treatment of a sinus headache. The trial included 83 patients with a sinus headache, based on American Academy of Otolaryngology – Head and Neck Surgery definitions, 44 randomized to conventional endoscopic sinus surgery and 35 to balloon ostial dilation. In the balloon dilation group, 23 patients were “only frontal sinus balloon” patients, in which balloon catheters were the only tools used for frontal sinus sinusotomy, and 12 were “hybrid,” in which balloon catheters and traditional ESS were used concurrently. It was not specified how patients were selected for these groups. At 6-month follow-up, SNOT-22 scores improved from 28.6 (baseline) to 7.8 in the endoscopic sinus surgery group and from 27.3 (baseline) to 5.3 in the balloon dilation group; improvements in both groups were statistically significant (p<0.001).

An RCT from Turkey (2011) reported on physiologic outcomes. Twenty patients were randomized to removal of the uncinate process via FESS or to balloon sinus ostial dilation as a stand-alone procedure. The main outcome measures were co₂ concentration in the sinuses and maximum sinus pressure, both intended as surrogate measures for sinus ventilation. The co₂ concentration decreased in both study arms to a similar degree. The maximum sinus pressure decreased in the FESS group but did not change in the balloon sinus ostial dilation group.
Another RCT, published by Achar et al (2012), enrolled 24 patients with CRS who had failed medical therapy and were scheduled for surgery. Patients were randomized to balloon dilation or to FESS and followed for 24 weeks. The primary outcome measures were changes in SNOT-20 scores and clearance time using the saccharin test. Both groups improved significantly on both measures. The degree of improvement was greater for the balloon dilatation group than for the FESS group on both the SNOT-20 score (43.8 vs 29.7, p<0.03) and on the saccharin test score (7.5 vs 3.5, p=0.03). Adverse events were not reported.

Bozdemir et al (2011) published a small study of 10 patients with nasal polyposis, in which 1 nasal passage was treated with FESS and the other with balloon sinus ostial dilation. All procedures were performed by the same surgeon, and polypectomy was performed before FESS or balloon sinus ostial dilation in all patients. Outcome measures included sinus patency, as measured by computed tomography (CT) scan (Lund-Mackay classification) or repeat endoscopy (Mackay grading). At 10 days postprocedure, there were improvements in both groups on measures of patency, but no differences between groups.

**Nonrandomized Comparative Studies**

A large number of nonrandomized comparative studies have evaluated balloon ostial dilation. Given the availability of RCT evidence, these studies do not provide significant additional evidence on the efficacy of balloon ostial dilation.

**Section Summary: Balloon Ostial Dilation as a Stand-Alone Procedure vs FESS Alone**

A number of randomized trials have compared balloon ostial dilation as a stand-alone procedure with FESS. These trials have generally reported that short-term outcomes with balloon ostial dilation are similar to those with FESS. Only 1 RCT, the REMODEL trial (105 patients randomized), was likely to have adequate power to detect group differences. It reported the noninferiority for the change in SNOT-20 scores and the superiority for balloon ostial dilation on postoperative recovery and pain medication use. The trial had methodologic limitations, including lack of blinded outcome assessment and differential dropout rates. This evidence shows some but limited support for balloon ostial dilation as an alternative to FESS in patients with CRS.

**Balloon Ostial Dilation as an Adjunct to FESS Vs FESS Alone**

Two RCTs identified have evaluated the incremental benefit of balloon ostial dilation plus FESS compared with FESS alone.

Hathorn et al (2015) reported on results of a single-blinded, randomized trial of balloon dilation with the Ventera Sinus Dilation System as an adjunct to frontal sinusotomy (Draf IIA) in which each patient served as his or her own control. The Draf IIA procedure involves a more extensive drainage procedure with resection of the floor of the frontal sinus. Thirty patients with CRS were randomized to the right or left balloon sinus dilation in conjunction with frontal sinusotomy. Both groups had high (30/30) rates of sinus ostia patency at 3
months postprocedure. Several procedure-related factors differed between groups: the hybrid (balloon sinuplasty) procedures were significantly shorter (655 seconds vs 898 seconds; 95% CI for difference, 30.9 to 454.4 seconds; p=0.03) and associated with less estimated blood loss (53 mL vs 91 mL; 95% CI for difference, 8.8 to 57.5 mL; p=0.008).

A double-blinded RCT of balloon sinus ostial dilation as an adjunct to FESS vs FESS alone was published by Plaza et al (2011). This trial enrolled 34 patients with CRS who were refractory to intensive medical management. Patients were randomized to a “hybrid approach” that included balloon sinus ostial dilation of the affected frontal recess along with traditional FESS of other paranasal sinuses, or to traditional FESS with the Draf I procedure. In both groups, an anterior ethmoidectomy was performed. A posterior ethmoidectomy and/or sphenoidotomy were performed as required by intraoperative assessment in both groups. Outcome measures at 12-month follow-up included symptoms, the Rhinosinusitis Disability Index, CT results of sinus patency, and the permeability of the frontal recess, as assessed by office endoscopy. One dropout was reported in each group, leaving 16 patients per group for analysis. For both groups, there were improvements in symptoms, standardized rhinosinusitis scoring indices, and CT patency, but no differences between groups. Rates for the 12-month outcome of endoscopic patency were 73% in balloon sinus ostial dilation patients and 63% in FESS patients. The published trial contained contradictory statements on whether this difference was statistically significant. The lead trialist clarified that the difference reported in the results for endoscopic patency was not statistically significant (G. Plaza, personal communication, April 2012). There were no major complications reported.

**Section Summary: Balloon Ostial Dilation as an Adjunct to FESS vs FESS Alone**

Two RCTs evaluating balloon ostial dilation as an adjunct to FESS were identified. Both suggested that the addition of balloon ostial dilation to traditional procedures can be done without adverse effects. One trial reported improved procedure times and less blood loss with balloon ostial dilation, although it is not clear whether the procedure time and blood loss were evaluated by a blinded observer. Both trials reported no significant differences between the hybrid and standard approaches in terms of sinus ostia patency.

**Balloon Ostial Dilation for Treatment of Chronic Rhinosinusitis**

**Balloon Ostial Dilation as a Stand-Alone or Adjunct Procedure**

**Single-Arm Studies**

Some single-arm studies have reported follow-up beyond 2 years for balloon ostial dilation and are described here. Bolger et al (2007) reported on outcomes at 24 weeks from a prospective, multicenter study of balloon sinus ostial dilation. In this study, 115 patients, for whom FESS was recommended, received treatment with the balloon catheter. Sinusotomy was attempted in 358 sinuses, and cannulation was successful in 347. Ostia patent rates were assessed at weeks 1, 12, and 24; at 24 weeks, 304 (88%) of the 347 sinuses were evaluated. While only five were nonpatent, the status of 18% was reported as indeterminate.
Patients’ symptoms as measured by SNOT-20 scores also improved posttreatment. The device malfunctioned in 12 (3.4%) of 358 cases, the balloon ruptured in 7 cases, and the catheter tip malfunctioned in 4 cases. The authors indicated that there were no serious adverse events.

The additional follow-up to 2 years has been reported for a subset of the 115 patients in the previous study. At the 1-year follow-up, 70 (61%) of the 115 patients remained in the study. Of the 66 patients who had follow-up nasal endoscopy, 85% of sinus ostia were patent; however, by adding results of CT scans showing improvement, 92% were judged to have functional patency. The report on clinical symptoms at 2-year follow-up involved a similar subset of patients (N=65). In this longer term study, in which 34 patients had only balloon treatment, 85% of patients had improved symptoms. Revision treatment was required in 3.6% of sinuses involving 6 (9%) of 65 patients.

A second prospective multicenter, single-arm study of balloon sinus ostial dilation in refractory rhinosinusitis was published by Stankiewicz et al (2010). They reported 1-year follow-up data of the Balloon Remodeling Antrostomy Therapy (BREATHE I) study. In it, 30 patients received balloon dilation of the ethmoid infundibulum using the FinESS system, a transantral dilation approach via the canine fossa. The primary outcome measure was patient-reported quality of life measured using the SNOT-20. Average overall symptom score at baseline was 2.9. At 3, 6, and 12 months postintervention, average overall symptom scores were 0.7, 0.8, and 0.8, respectively.

Two-year results from the BREATHE study were reported in 2012. At that time, 59 patients were treated with balloon sinus ostial dilation, with a mean follow-up of 27 months. Mean SNOT-20 scores improved from 2.65 at baseline to 0.79 at the longest follow-up. This report also discussed measures of functional impairment using the Work Limitation Questionnaire and the Work Productivity and Activity Impairment Questionnaire. Mean scores on the Work Limitation Questionnaire for overall productivity loss decreased from 8% at baseline to 2.5% at longest follow-up (estimates from graphical representation), and this pre- and postchange was statistically significant (p<0.001). Similar improvements were reported on other parameters of the Work Limitation Questionnaire and Work Activity Impairment Questionnaire.

Series with shorter follow-up have also been published. For example, Soler et al (2017) reported results of a single-arm study evaluating stand-alone balloon sinus dilation for CRS in children ages 2 to 21 years. At 6-month follow-up, results of the Sinus and Nasal Quality of Life Survey were significantly improved compared with baseline (p<0.001).

**Summary of Evidence**
For individuals with chronic rhinosinusitis who receive balloon ostial dilation as a stand-alone procedure, the evidence includes systematic reviews and RCTs. Relevant outcomes are symptoms, change in disease status, quality of life, and treatment-related morbidity. The available systematic reviews (including a
Cochrane review and a TEC Assessment) have concluded that, although nonrandomized evidence has suggested balloon ostial dilation has similar outcomes to FESS, evidence from randomized trials is needed to demonstrate an improvement in outcomes for patients treated with balloon ostial dilation. Since the publication of those systematic reviews, an additional RCT (REMODEL) has been published. It assessed 105 patients, reporting short-term improvement in symptoms similar to those seen with FESS and potential advantages for balloon ostial dilation on postoperative recovery time and pain medication use. Limitations of the REMODEL trial included its unblinded outcomes assessment and differential dropout between groups. Other trials have provided limited additional evidence. The evidence is insufficient to determine the effects of the technology on health outcomes.

For individuals with chronic rhinosinusitis who receive balloon ostial dilation as an adjunct to FESS, the evidence includes 2 RCTs and single-arm series. Relevant outcomes are symptoms, change in disease status, quality of life, and treatment-related morbidity. Neither available RCT reported significant clinically meaningful benefits associated with the addition of balloon ostial dilation to FESS. The evidence is insufficient to determine the effects of the technology on health outcomes.

**Supplemental Information**

**Clinical Input From Physician Specialty Societies and Academic Medical Centers**

While the various physician specialty societies and academic medical centers may collaborate with and make recommendations during this process, through the provision of appropriate reviewers, input received does not represent an endorsement or position statement by the physician specialty societies or academic medical centers, unless otherwise noted.

**2013 Input**

In response to requests, input was received from 2 specialty societies and 6 academic medical centers while this policy was under review in 2013. Input was mixed on whether balloon ostial dilation should be medically necessary, either as a stand-alone procedure or as an adjunct to functional endoscopic sinus surgery (FESS). There was no consensus on subpopulations of patients with chronic rhinosinusitis who might benefit from balloon ostial dilation. There was a consensus that randomized controlled trials should compare balloon ostial dilation with standard care in order to determine efficacy.

**2011 Input**

In response to requests, input was received from 2 physician specialty societies and 6 academic medical centers while this policy was under review in 2011. Input was mixed. A number of reviewers agreed that balloon ostial dilation was investigational. These reviewers commented about the need for additional trials to compare outcomes with standard approaches. Comments were made on the lack of selection criteria for the use of the balloon catheter. Reviewers also noted that
the current studies did not permit separating the results for the use of the balloon ostial dilation from concurrent FESS because most studies used both techniques.

2008 Input
In response to requests, input was received from 2 physician specialty societies and 2 academic medical centers while this policy was under review in 2008. Input from 1 specialty society did not specifically address the clinical aspects of balloon ostial dilation but made comments related to coding. Another specialty society noted concerns due to lack of controlled studies and also commented that the long-term objective follow-up (eg, computed tomography scans) was on a limited number of patients. Input from 2 academic centers indicated this treatment was not investigational but should be viewed as another surgical tool for the treatment of chronic sinusitis.

Practice Guidelines and Position Statements

National Institute for Health and Care Excellence
A 2008 guidance on balloon catheter dilation of paranasal sinus ostia from the National Institute for Health and Care Excellence has stated: “Current evidence on the short-term efficacy of balloon catheter dilation of paranasal sinus ostia for chronic sinusitis is adequate and raises no major safety concerns.” In 2016, the Institute published a recommendation on the use of the XprESS Multi-Sinus Dilation System for the treatment of chronic rhinosinusitis:

1.1 “The case for adopting the XprESS multi-sinus dilation system for treating uncomplicated chronic sinusitis after medical treatment has failed is supported by the evidence. Treatment with XprESS leads to a rapid and sustained improvement in chronic symptoms, fewer acute episodes and improved quality of life which is comparable to functional endoscopic sinus surgery (FESS).

1.2 XprESS should be considered in patients with uncomplicated chronic sinusitis who do not have severe nasal polyposis. In these patients, XprESS works as well as FESS, is associated with faster recovery times, and can more often be done under local anaesthesia.”

American Academy of Otolaryngology – Head and Neck Surgery
In 2017, the American Academy of Otolaryngology – Head and Neck Surgery updated its statement on balloon ostial dilation, reaffirming its 2010 position statement: “Sinus ostial dilation ... is a therapeutic option for selected patient with chronic rhinosinusitis.... This approach may be used alone ... or in conjunction with other instruments....”

In 2015, the Academy’s Foundation updated its 2007 clinical practice guidelines on adult sinusitis, which do not discuss surgical therapy or use of balloon sinuplasty.
American Rhinologic Society
A position statement, revised in 2017, from the American Rhinologic Society, stated that sinus ostial dilation is “a therapeutic option for selected patients with chronic rhinosinusitis (CRS) ... who have failed appropriate medical therapy.”

U.S. Preventive Services Task Force Recommendations
Not applicable.

Medicare National Coverage
There is no national coverage determination. In the absence of a national coverage determination, coverage decisions are left to the discretion of local Medicare carriers.

Ongoing and Unpublished Clinical Trials
Some currently unpublished trials that might influence this review are listed in Table 1.

ICD10 Codes

J32.0- Chronic sinusitis code range
J32.9

Beginning in 2011, there are specific category I CPT codes for these procedures (31295-31298). These codes may be used to describe balloon sinuplasty when no other surgical intervention has been performed on the same sinus site.

Prior to 2011, and perhaps in the future, this procedure might be coded as an unlisted sinus procedure (31299). It could be submitted alone or along with other nasal/sinus endoscopy codes.

If balloon sinuplasty is performed in conjunction with cutting tools such as curettes and forceps, the procedure might be coded using the CPT codes for nasal/sinus endoscopy with maxillary antrostomy (31256), nasal/sinus endoscopy with frontal sinus exploration (31276), or nasal/sinus endoscopy with sphenoidectomy.
Plans should be aware of this possibility. In this instance, the balloon dilation would be considered inclusive/incidental to the procedure.

In the Medicare outpatient hospital setting, HCPCS code C1726 may be used for the device.

Between 2007 and 2011, a specific HCPCS S code for the procedure was available S2344 Nasal/sinus endoscopy, surgical; with enlargement of sinus ostium opening using inflatable device (i.e., balloon sinuplasty)
